
INTEGRATION BRIEF · CONFIDENTIAL

TACTIK AI Integration Brief

Prepared for Python Technologies following the call of 21 September. What the platform is, what it produces, where an implementation partner works, and a first scoped engagement with objective acceptance criteria. Written to be quoted, not to be admired.

From
Santiago Maspons, TACTIK AI

Python Technologies

Status
Covered by mutual NDA in force

Date
22 September 2026

PURPOSE

What this document covers

Following our call on 21 September, this sets out what the TACTIK platform is, what it produces, where an implementation partner would work, and what a first scoped engagement could look like.

It is written for an engineering reader. It describes interfaces, deployment surfaces and acceptance criteria rather than product positioning. Where the platform is incomplete, that is stated plainly, because a scope you cannot quote is of no use to either of us.

SCOPE OF DISCLOSURE

This document covers the integration perimeter: interfaces, data contracts, deployment surfaces, and the output artifact. It does not cover the reasoning layer, the behavioural profile authoring method, the adjudication logic or the scoring model. That boundary is the one already reflected in the mutual NDA, and it is not a negotiating posture: none of it is required to scope, quote or deliver the work described in Section 5.

SECTION 01

What the platform is

A behavioural simulation platform that puts an executive across the table from a modelled counterparty, then returns a scored, evidence-backed record of the encounter.

STACK AS DEPLOYED

LAYER	TECHNOLOGY	NOTES
Frontend	React 18, TypeScript 5, Vite	Roughly 80 routes in production. Tailwind, shadcn/ui, Recharts.
Backend	Supabase (PostgreSQL)	Row-level security, auth, storage, realtime.
Compute	Deno edge functions	Simulation, adjudication, debrief generation, research pipeline.
Reasoning	Model-agnostic	Provider abstracted behind an internal interface. Not part of this scope.
Video (planned)	Conversational video, WebRTC	Photorealistic counterparty rendering. Integration not yet validated in production.
Hosting	Lovable, Cloudflare	Live at tactikai.co.

The platform is live and running in production today. The work discussed below is hardening and extending it, not building it from zero.

What it produces

The output is the product. Everything else is machinery that exists to generate it reliably.

The attached case file is a real artifact from a real session, not a mock-up. It is the specification target: whatever is built must produce this, reliably, at acceptable latency and cost.

COMPONENT	CONTENT	WHY IT MATTERS FOR INTEGRATION
Audit header	ledger UUID, trace id, timestamp, transcript hash, engine version provenance	Every figure must be traceable to a specific engine build. Version provenance distinguishes the build that ran the session from the build that compiled the file.
In-turn ledger	append-only, turn-indexed	Written during the session, not reconstructed afterwards. This is the hardest non-functional requirement in the system.
Scored axes	six, one excluded by design	Five score the participant. The sixth measures whether the modelled counterparty stayed true to its profile, and is deliberately kept out of the composite.
Forensic audit	per-turn, quotation-backed	No scored row exists without a verbatim quotation behind it.
Rendered file	PDF, six pages	Server-side rendering pipeline. Charts are generated from ledger rows, never hand-placed.

Two properties are non-negotiable and shape the architecture more than anything else. **The ledger is written in-turn**, because a record reconstructed after the fact is a narrative rather than evidence. And **unmeasured never reads as clean**: an axis the system could not observe is reported as undetermined and excluded from the composite rather than scored as zero.

SECTION 03

Current state, stated plainly

CAPABILITY	STATUS	DETAIL
Text simulation, end to end	WORKING	Human against a modelled counterparty. Runs at zero marginal video cost.
Behavioural profile persistence	WORKING	Profiles, sessions, message history, caching with staleness scoring.
Adjudication and scoring	WORKING	Produced the attached case file.
Case file rendering	WORKING	Server-side PDF generation from ledger rows.
Guest session persistence	GAP	Guest runs hold state in memory to avoid row-level security friction, so an evaluator session leaves no auditable record. This needs an ephemeral persistence path.
Credential broker	OUTSTANDING	Third-party API keys must move off the browser bundle and behind an edge function issuing short-lived tokens.
Deterministic session teardown	OUTSTANDING	Metered video sessions must terminate on unmount, on timeout and on participant absence. Without this, an abandoned browser tab bills indefinitely.
Live video latency validation	OUTSTANDING	Measured median reply latency is around 3.2s with observed spikes to 14.4s, correlated with an in-turn research step. Live video requires this under roughly 1.2s at the 95th percentile.
Conferencing surfaces	PLANNED	Zoom, Microsoft Teams and Google Meet, for observer participation in live sessions.

The last four rows are the work. They are infrastructure and hardening problems rather than product-definition problems, which is why they are a good fit for an external implementation partner and why they can be scoped against objective acceptance criteria.

SECTION 04

Integration perimeter

What a partner works on, and what stays inside TACTIK. The boundary is drawn on necessity, not secrecy.

IN SCOPE FOR A PARTNER

- **Credential brokering and session lifecycle.** Edge function issuing ephemeral tokens; hard duration caps; teardown on unmount, timeout and absence; one concurrent metered session per user.
- **Video layer integration.** WebRTC session establishment, dual-track binding, provider abstraction behind the existing interface, mock provider for zero-cost testing.
- **Conferencing surfaces.** Zoom, Teams and Meet participation so observers can watch a live session without the participant screen-sharing.
- **Observability.** Latency instrumentation per pipeline stage, inference spend telemetry per tenant, alerting on cost and on session leakage.
- **Persistence and tenancy.** Ephemeral persistence for evaluator sessions, row-level security policies, retention and deletion.
- **Rendering pipeline.** Hardening the server-side case file generation, canonical hashing of the source transcript, deterministic output.

OUTSIDE THE PERIMETER

The reasoning layer, the behavioural profile authoring method, the adjudication logic, the scoring model, the prompt architecture and the internals of the sealing pipeline remain with TACTIK and are not licensed. This is already reflected in the mutual NDA received from your side, which preserves TACTIK intellectual property, prohibits reverse engineering and grants no license.

This boundary is practical rather than defensive. Every item in the in-scope list can be specified, built, tested and accepted without reference to any of it. A partner integrates against declared interfaces and measurable acceptance criteria.

SECTION 05

Proposed first engagement

Narrow, fixed price, objectively testable. Designed so both sides learn whether this works before either commits further.

DELIVERABLE	ACCEPTANCE CRITERION
Credential broker	No third-party key present in the shipped browser bundle, verified by inspection. Client receives a room reference and nothing else.
Deterministic teardown	Sessions terminate on component unmount, on duration cap and on participant absence. Demonstrated by a test that abandons a session and shows billing stops.
Latency instrumentation	Per-stage timings recorded and queryable. A 95th-percentile figure reportable for any date range.
Ephemeral evaluator persistence	A guest session produces a retrievable ledger and case file, deleted automatically after a defined window.
One conferencing surface	Observers join a live session through a single named platform and see the session feed as a participant.

Indicative duration four to six weeks. Fixed price against these criteria rather than time and materials. If the engagement works, the natural follow-on is the live video latency work, which is the gate on the whole video modality and is better attempted once the cost controls above are in place.

SECTION 06

What we need from you to proceed

- **A named technical lead** for the engagement, with relevant WebRTC and Supabase or Postgres experience.
- **Confirmation that you work fixed-price** against defined acceptance criteria, rather than time and materials only.
- **Your assessment of the scope in Section 5**, including anything you consider mis-scoped or missing. A partner who accepts a scope uncritically is not the partner we want.
- **Indicative pricing and earliest start date.**
- **Confirmation of security posture** for handling a client's declared commercial thresholds, which are the most sensitive data the platform holds.

The attached case file is the specification target. It is a reference case built against a synthetic counterparty and a synthetic evaluated party, produced by the live system. It is not a client engagement and should be treated as a technical exhibit.

TACTIK AI · prepared following the call of 21 September 2026 · covered by the mutual NDA in force
 · commercial thresholds and reasoning methodology excluded by design
